AtlasVision X1 试点评估摘要

星河科技在上海港湾实验室开展了为期六周的虚构试点，用于评估AtlasVision X1在受控光照条件下识别表面缺陷的能力。设备安装在第二条传送工位上方，通过三个蓝色光学传感器采集重叠视角，并使用一个琥珀色状态灯提示样品正在等待人工复核。

试验共使用五百个合成样品，覆盖划痕、涂层缺口、位置偏移和无缺陷对照。原生文本、OCR辅助和视觉语言三种流程分别获得百分之八十八、百分之九十一和百分之九十四点二的分类准确率。视觉语言流程在需要比较样品边缘和夹具位置的任务上表现更好，但反光表面仍然造成了若干误报。

本次评估要求每条结论都能回溯到原始图片、页面或图像区域。仅由视觉信息支持的数量、身份和空间关系不得自动写入知识图谱，必须先经过证据校验和人工审核。报告中的公司、人员、设备、实验室和数据均为虚构内容，仅用于多模态解析测试。

Pilot review memorandum

Nebula Technology completed a six-week fictional pilot of AtlasVision X1 at Harbor Laboratory. The equipment was mounted above the second conveyor station and captured three overlapping optical views of each sample. An amber status light indicated when a candidate observation was waiting for human review.

Five hundred synthetic samples were divided across scratches, coating gaps, alignment errors, and no-defect controls. The vision-language workflow classified 471 samples correctly, but glossy surfaces produced false positives and small boundary defects were sometimes missed. These limitations prevented the team from recommending autonomous acceptance of safety-critical parts.

Every observation retained a source hash and an image-region reference. Visual-only counts, identities, and spatial relations required explicit review before graph commit. All names, measurements, and operational details in this memorandum are fictional and exist solely to test OCR, evidence recovery, and multimodal extraction.
